

Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

connected with the iron-industry, but also descriptions of the apparatus and manipulations especially adapted to the work.

A fuller discussion of the advantages and defects of the several methods given for the determination of a single element would have added to the user's satisfaction.

One is surprised to find in a work so excellent a table of atomic weights in which recent recalculations and redeterminations are ignored. According to this table, $\text{Al}=27.5$, $\text{Sb}=122$, $\text{Mn}=55$, $\text{Pt}=197.18$, etc. The error naturally extends to the table of factors, which are calculated on the basis of these atomic weights. Thus the factor for Al from Al_2O_3 is .53398, instead of .53010 as it would be with Clarke's value, $\text{Al}=27.075$ ($\text{O}=16$).

The mechanical execution of the book is, on the whole, superior to any thing we have had the good fortune to see in the way of laboratory handbooks. Heavy, fine paper, admirable press-work, and a party-colored binding make the book pleasant to the eye and hand, and—expensive. It is indeed almost too fine and costly to expose to the rude chance of laboratory disfigurement. It may be, however, that author and publisher hope, through its full-dress appearance, to promote a feeling of greater respect for nicety of manipulation in the chemists into whose hands it may come.

The book is unusually free from typographical errors; but we notice a slip of the proof-reader's on pp. 55, 56, 57, and 63, where the references to Fig. 45 should read H instead of D.

First Lessons in English. By F. B. GREENE. Philadelphia, Cowperthwait & Co. 16°.

ONE of the most difficult studies for most young persons is grammar. A few, whose minds are fitted to readily grasp abstract ideas, learn it easily and with pleasure; but to the majority it is at first irksome. This is partly due to the habit of English grammarians of laying down a mass of rules borrowed from the classical languages, and having but little application to our own tongue; but it is also in part due to the abstract and formal character of grammatical treatises, which are ill adapted to the minds of children. To remove this difficulty and make the introduction to grammar easier, books have been prepared of late years on the inductive principle, and teaching the rudiments of the science by example. Rules and technical terms are very sparingly used, and the pupil is taught the parts of speech and the construction of the sentence in so simple a way that he can hardly fail to understand them. The book before us is one of this class, and, though nothing but actual use in the classroom can accurately test its value, it seems to be well adapted to its purpose. It is illustrated, so as to make it attractive to very young pupils; and the lessons and examples are of the simple character that such pupils need. Such a work is certainly a great improvement on the elementary grammars of former days.

Old and New Astronomy. Parts I.-V. By RICHARD A. PROCTOR. London and New York, Longmans, Green, & Co. 4°.

THE present work, the first instalments of which have reached us, is intended to give an account of the science of astronomy and of its history to the general student. The work is admirably adapted to this purpose, Proctor's theories and arguments being set forth very clearly, and being illustrated by numerous good and very instructive cuts, which pre-eminently enhance the value of the book. In a brief introduction the author states his object. "It is as a subject for study and contemplation as a means for training and exercising, but likewise for ennobling and purifying the mind, that astronomy should be studied by all. It is the celestial science as viewed and studied by philosophers, as Newton and Herschel, that I propose to contemplate in the present volume." In the first chapter the history of the methods of observing heavenly bodies is described, in which discourse Proctor expounds his curious concept that the Egyptian pyramids were nothing else than immense observatories. The development of these methods is traced up to the present time. The next chapter contains studies of the earth's shape. The various proofs of the earth's curvature are explained by novel figures, among which we call attention to the telescopic view of a 'hull down' ship seen indistinctly beyond the sharply defined horizon, thus proving that it is farther distant than the horizon. In the discussion of the sun, moon, and planets, their apparent motions are first treated; and after an exhaustive explanation of

the ancient theories, and the paths of the planets relatively to the earth, supposed to be at rest, Kepler's system is described and explained. Of particular interest is Proctor's elementary deduction of the perturbing action of the sun on the moon, which is used in explaining the cause of the tides. The fifth instalment treats of the methods and results of measuring and weighing the solar system. The book is very beautifully printed, and the instalments are following each other very rapidly. The matter is treated very attractively, and the mathematical deductions, which are contained in notes, are so arranged as to be intelligible to anybody who has an elementary knowledge of it.

NOTES AND NEWS.

RICHARD ANTHONY PROCTOR died in this city on Sept. 12, of yellow-fever, which he had contracted in Florida. Proctor was born at Chelsea, England, on March 23, 1837. Early in life he devoted himself to astronomy, and was a very fruitful writer. His first book was on 'Saturn and its System.' In the United States he is largely known to the public through his lectures, which he delivered in most of the larger cities. His first visit to our country was in 1873-74. He was eminently successful as a popular writer, and knew well how to make the difficult problems of astronomy attractive and intelligible to the general reader. His last work, 'Old and New Astronomy,' which is being published, is a splendid specimen of his enthusiasm for his science and of his success in imparting it to his readers.

—The Appalachian Mountain Club plans an excursion to Mount Washington, Mass.; the party, which will be limited to fifty in number, to leave on Friday morning, Sept. 28.

—E. Dubois read recently, before the French Academy of Sciences, a paper on the satellites of Mars which were discovered in 1877 by Asaph Hall. It appears remarkable, that notwithstanding the numerous observations of the planet, and notwithstanding their rapid motion and close proximity to it, they were not discovered sooner. Dubois believes that such would undoubtedly have been the case if they had existed. He expresses the opinion that two of the telescopic planets which occupy the zone between Mars and Jupiter approached the former so near that they have become its satellites. He also says that several others of these bodies may become satellites of Mars in course of time.

—F. S. Mansfield, attaché to the United States Legation in Japan, visited the scene of the eruption of the Bantaisan in Japan, of which a full report was given in the last issue of *Science*. His account, which was printed in the *Atlanta Constitution*, Aug. 26, contains the following additional details: On Sunday, the 15th of July, rumblings were heard and earth-tremors felt in the vicinity of the Bantaisan. The first disturbance noticed occurred at about 7 A.M., and was followed by three earthquake shocks at intervals of ten minutes, when there occurred a loud explosion, the noise of which the people compared to the report of thousands of cannons discharged simultaneously. At 10 A.M. the eruption was at its height, and by 4 P.M. it was over. The Japanese Government has set up a temporary hospital in a schoolhouse for the treatment of the wounded, and has organized a relief committee to look after the homeless and to recover the bodies of those who had been killed. The number of people who lost their lives by the disaster was, according to the official statement from the government relief station at Inawashiro, 518, the bodies of 70 of whom had been found, while 41 persons had been injured, and were then in the hospital at Inawashiro. The eruption occurred on the eastern side of the principal peak of Bantaisan. A portion of the smaller peak was carried away. The mud then filled up the side of the mountain, not only on the eastern side, but on the northern side as well, running down in a stream to the valley below. At the foot of the mountain each stream was about half a mile wide, gradually narrowing toward the top. The main eastern stream was divided about halfway up the mountain by a ridge, and came down in two separate volumes, the one continuing east, while the other branch came down on the southern side of the mountain, the latter stopping in the very small hamlet of Minemura, which was partially destroyed by the mud covering completely some of the houses.
